Volpe National Transportation Systems Center has been conducting a long-term research project on rail integrity. Over the past 20 years the development of high strength alloys and the use of lubrication has lead to a significant prolongation of rail wear life [1 Although wear remains the principal life limiting factor the focus of attention with respect to rail safety and integrity has shifted to crack failure induced by long-term rolling contact fatigue. This is additionally amplified by the strong interest of the industry to further increase axle loads and speed. A main source of such service-induced damage is the concentration of very high contact stresses on the rail which leads to subsurface plastic deformation with accumulation of residual stresses of the order of the yield stress. The immediate damage effects are fatigue crack initiation and growth. Secondary damage effects are initiated by the feeding of material due to plastic flow into the high wear rate gage face as well as longitudinal corrugations which form a wavy structure on the running surface of the rail. The primary mechanisms extend both to the formation and opening of surface cracks as well as of horizontal cracks located about 6 to 7 mm below the surface. The latter ones are commonly referred to as shell defects and they are comparatively benign in nature since they do not cause rail failure directly but tend to grow in an in-plane direction well below the surface. However, in the case of a preferred rolling direction...
