The first involves a careful examination of the NGDC historical tsunami database which resulted in a qualitative tsunami assessment based on the distribution of runup heights and the frequency of tsunami runups. We characterize the tsunami hazard by first determining the number of individual tsunamis booked in each State or territory and then binning the results into five categories of runup amplitudes—Undetermined runup height, 0.01 m to 0.5 m, 0.51 m to 1.0 m, 1.01 m to 3.0 m, and greater than 3.0 m. Based on the total spread of events, runup amplitudes, and earthquake potential, we assigned a subjective hazard from very low to very high. These assessments recognized that tsunami runups of a few tens of centimeters have a lower hazard than those with runups of a few to many meters. Our database search reinforces the common understanding that the U.S. Atlantic coast and the Gulf Coast States have experienced very few tsunami runups in the last 200 years. In fact, Louisiana, Mississippi, Alabama, the...
