Excerpt from Laser Induced Damage in Optical Materials, 1972: Proceedings of a Symposium Sponsored by the American Society for Testing and Materials and by the National Bureau of Standards; June 14-15, 1972, Nbs, Boulder, Colorado 80302 Several important features of damage in thin film are beginning to emerge as a consequence of investigation. Due, in general, to the poor homogeneity of thin film, both in single layer and multilayer form, it is difficult to evaluate the respective role of absorption and electron avalanche. Whatever the operative mechanism, it is likely that it is sensitive to the local field strength which, in a multilayer dielectric, can exhibit pronounced spatial variation. The use of vapour phase mixtures enables film with a great variation in refractive index to be laid down with a minimum of thickness. This should provide a valuable technique for the study of film damage. It seems clear that by reducing the thickness in the film, the damage threshold can be raised. There is also evidence that damage in film is accompanied by an increase in light scattering, so that scattering measurement appears to provide a useful diagnostic tool.
